

159.352 Assignment 2

Tips on implementing

1. Get a bare-bones Next.js application working that is deployed on Vercel and can connect to MongoDB Atlas
2. Decide on a suitable data model—a possible schematic could be

In a relational database, **Schedules** and **Passengers** would be tables with **Bookings** acting as a junction table to record which passengers are on which flight.

In a NoSQL database like MongoDB, **Schedules** and **Passengers** would be collections. One document in **Schedules** could be the details for a single scheduled flight operating at a particular date and time. One document in **Passengers** could have the details for a particular passenger. As there is a “one-to-few” relationship between **Schedules** and **Passengers** the **Bookings** could be embedded within **schedules**.

3. Decide on your API endpoints. In particular, you may like to have an API that searches for all scheduled flights going from a given origin to a given destination that are operating between two given dates. A possible endpoint could be

`/api/schedules?date1=2026-06-10&date2=2026-06-30&orig=NZNE&dest=YSSY`

which would need to implemented in the route handler

`app/api/schedules/route.ts`

4. Implement the front end user interface
5. Implement styling

If need be, re-iterate steps (2)–(5).
